Weighted Graphs and Applications

Paul Fodor

CSE260, Computer Science B: Honors

Stony Brook University

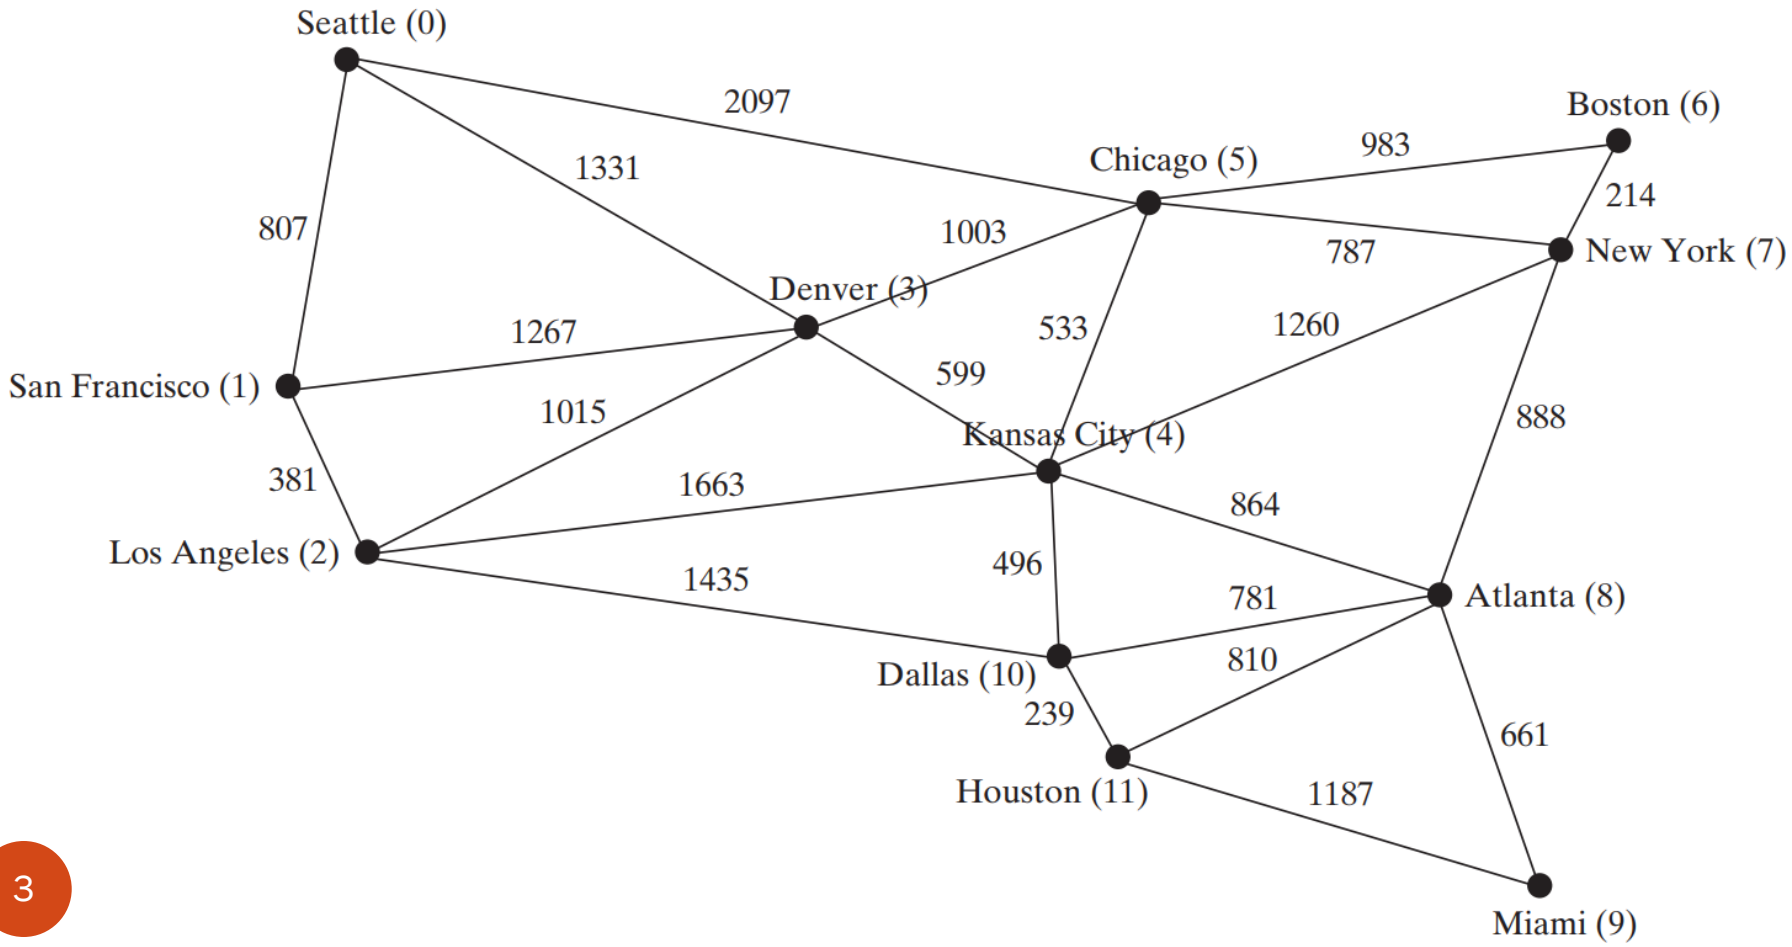
http://www.cs.stonybrook.edu/~cse260

Objectives

- To represent weighted edges using adjacency matrices and adjacency lists
- To model weighted graphs using the **`WeightedGraph`** class that extends the **`AbstractGraph`** class
- To design and implement the algorithm for finding a minimum spanning tree
- To define the **`MST`** class that extends the **`Tree`** class
- To design and implement the algorithm for finding single-source shortest paths
- To define the **`ShortestPathTree`** class that extends the **`Tree`** class
- To solve the weighted nine tail problem using the shortest-path algorithm

Weighted Graphs

- A graph is a ***weighted graph*** if each edge is assigned a weight
  - Assume that the edges represent the driving distances among the cities

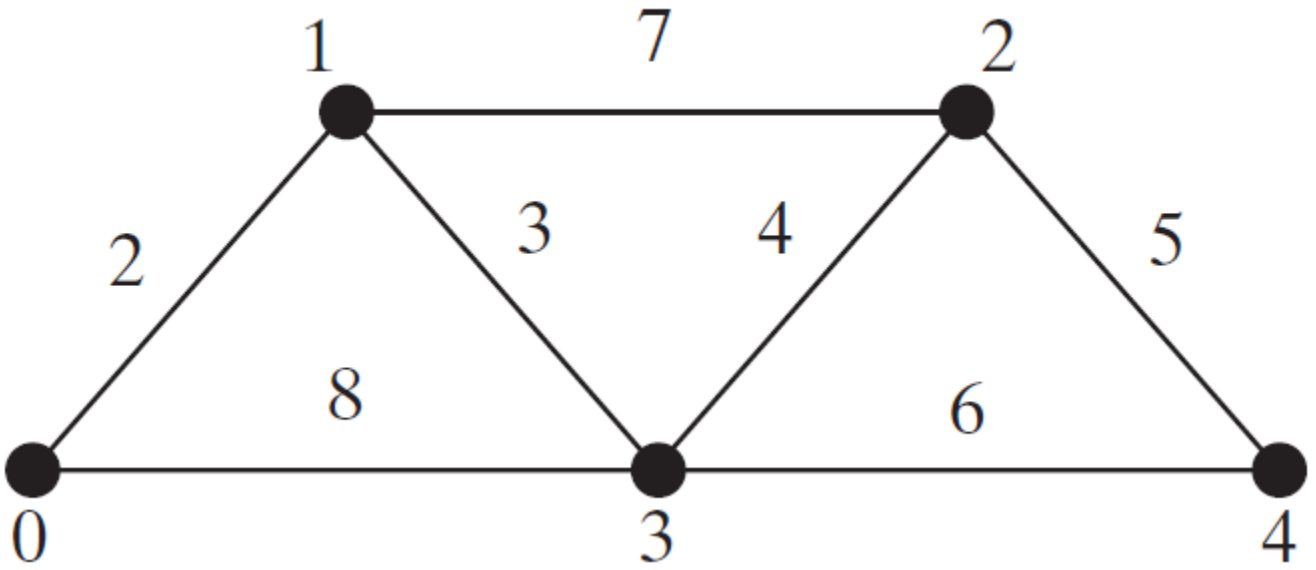


Representing Weighted Graphs

- Representing Weighted Edges
  - Edge Array
  - Weighted Adjacency Matrices
  - Adjacency Lists

Representing Weighted Edges: Edge Array

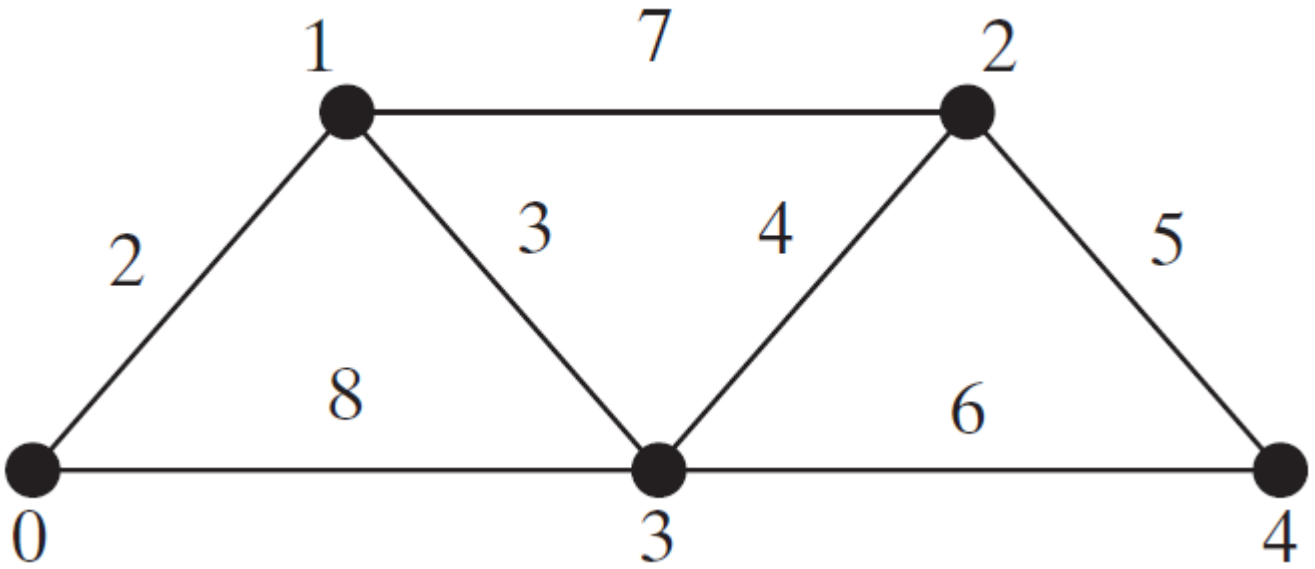
```
int[][] edges = {{0, 1, 2}, {0, 3, 8},
   {1, 0, 2}, {1, 2, 7}, {1, 3, 3},
   {2, 1, 7}, {2, 3, 4}, {2, 4, 5},
   {3, 0, 8}, {3, 1, 3}, {3, 2, 4}, {3, 4, 6},
   {4, 2, 5}, {4, 3, 6}
};
```



Weighted Adjacency Matrices

```
Integer[][] adjacencyMatrix = {
  {null, 2, null, 8, null },
  {2, null, 7, 3, null },
  {null, 7, null, 4, 5},
  {8, 3, 4, null, 6},
  {null, null, 5, 6, null}
```

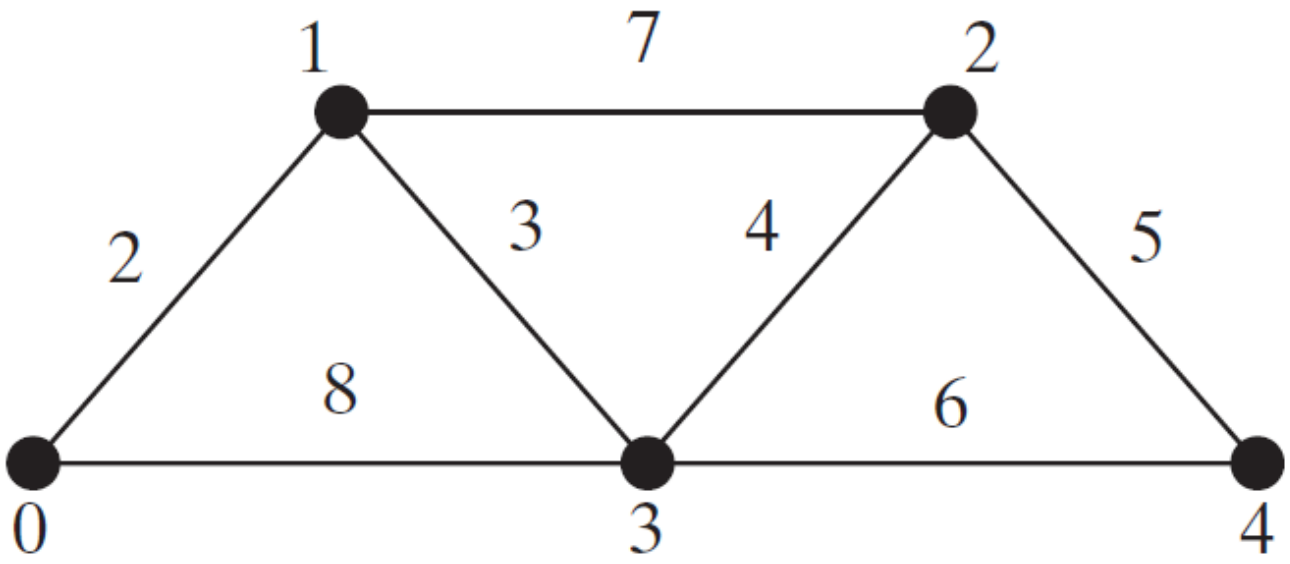
	0	1	2	3	4
0	null	2	null	8	null
1	2	null	7	3	null
2	null	7	null	4	5
3	8	3	4	null	6
4	null	null	5	6	null



Edge Adjacency Lists

```
java.util.List<WeightedEdge>[] list =
    new java.util.List[5];
```

list[0]	WeightedEdge(0, 1, 2)	WeightedEdge(0, 3, 8)		
list[1]	WeightedEdge(1, 0, 2)	WeightedEdge(1, 3, 3)	WeightedEdge(1, 2, 7)	
list[2]	WeightedEdge(2, 3, 4)	WeightedEdge(2, 4, 5)	WeightedEdge(2, 1, 7)	
list[3]	WeightedEdge(3, 1, 3)	WeightedEdge(3, 2, 4)	WeightedEdge(3, 4, 6)	WeightedEdge(3, 0, 8)
list[4]	WeightedEdge(4, 2, 5)	WeightedEdge(4, 3, 6)		



```
public class WeightedEdge extends AbstractGraph.Edge
    implements Comparable<WeightedEdge> {
  public double weight; // The weight on edge (u, v)

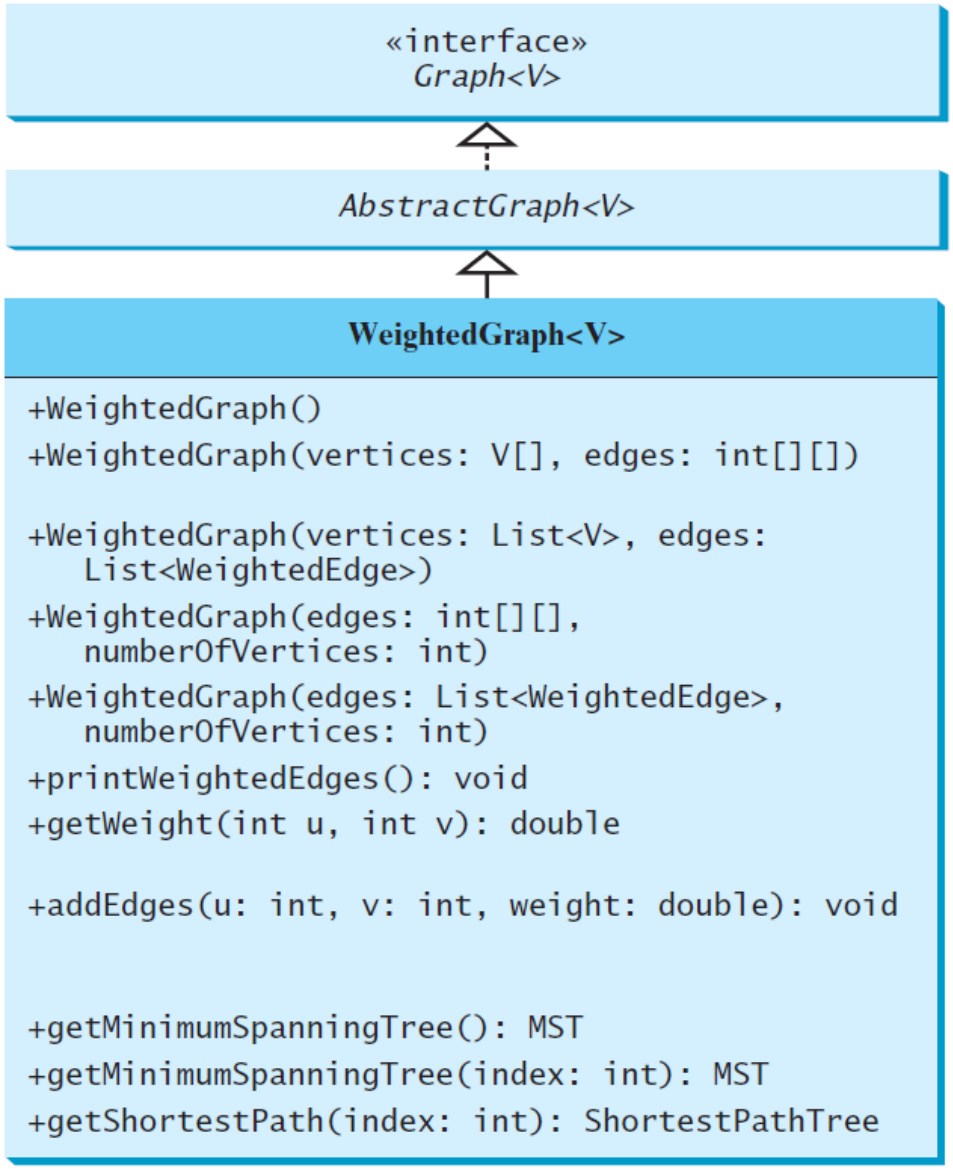
  /** Create a weighted edge on (u, v) */
  public WeightedEdge(int u, int v, double weight) {
    super(u, v);
    this.weight = weight;
  }

  /** Compare two edges on weights */
  public int compareTo(WeightedEdge edge) {
    if (weight > edge.weight) {
      return 1;
    }
    else if (weight == edge.weight) {
      return 0;
    }
    else {
      return -1;
    }
  }
}
```

Edge Adjacency Lists

For flexibility, we will use an array list rather than a fixed-sized array to represent **list** as follows:

```
List<List<WeightedEdge>> list =
    new java.util.ArrayList<>();
```



Constructs an empty graph.

Constructs a weighted graph with the specified edges and the number of vertices in arrays.

Constructs a weighted graph with the specified edges and the number of vertices.

Constructs a weighted graph with the specified edges in an array and the number of vertices.

Constructs a weighted graph with the specified edges in a list and the number of vertices.

Displays all edges and weights.

Returns the weight on the edge from u to v. Throw an exception if the edge does not exist.

Adds a weighted edge to the graph and throws an `IllegalArgumentException` if `u`, `v`, or `w` is invalid. If `(u, v)` is already in the graph, the new weight is set.

Returns a minimum spanning tree starting from vertex 0.

Returns a minimum spanning tree starting from vertex `v`.

Returns all single-source shortest paths.

```
import java.util.*;
public class WeightedGraph<V> extends AbstractGraph<V> {

  /** Construct an empty */
  public WeightedGraph() {
  }

  /** Construct a WeightedGraph from vertices and edged in arrays */
  public WeightedGraph(V[] vertices, int[][] edges) {
    createWeightedGraph(java.util.Arrays.asList(vertices), edges);
  }

  /** Construct a WeightedGraph from vertices and edges in list */
  public WeightedGraph(int[][] edges, int numberOfVertices) {
    List<V> vertices = new ArrayList<>();
    for (int i = 0; i < numberOfVertices; i++)
      vertices.add((V)(new Integer(i)));
    createWeightedGraph(vertices, edges);
  }

  /** Construct a WeightedGraph for vertices 0, 1, 2 and edge list */
  public WeightedGraph(List<V> vertices, List<WeightedEdge> edges) {
    createWeightedGraph(vertices, edges);
  }
```

```
/** Construct a WeightedGraph from vertices 0, 1, and edge array */
public WeightedGraph(List<WeightedEdge> edges, int numberOfVertices) {
  List<V> vertices = new ArrayList<>();
  for (int i = 0; i < numberOfVertices; i++)
    vertices.add((V)(new Integer(i)));
  createWeightedGraph(vertices, edges);
}

/** Create adjacency lists from edge arrays */
private void createWeightedGraph(List<V> vertices, int[][] edges) {
  this.vertices = vertices;
  for (int i = 0; i < vertices.size(); i++)
    neighbors.add(new ArrayList<Edge>()); // Create a list for vertices
  for (int i = 0; i < edges.length; i++)
    neighbors.get(edges[i][0]).add(
      new WeightedEdge(edges[i][0], edges[i][1], edges[i][2]));
}

/** Create adjacency lists from edge lists */
private void createWeightedGraph(List<V> vertices, List<WeightedEdge> edges) {
  this.vertices = vertices;
  for (int i = 0; i < vertices.size(); i++) {
    neighbors.add(new ArrayList<Edge>()); // Create a list for vertices
  }
  for (WeightedEdge edge: edges) {
    neighbors.get(edge.u).add(edge); // Add an edge into the list
  }
}
```

```
  /** Return the weight on the edge (u, v) */
  public double getWeight(int u, int v) throws Exception {
    for (Edge edge : neighbors.get(u)) {
      if (edge.v == v) {
        return ((WeightedEdge)edge).weight;
      }
    }
    throw new Exception("Edge does not exit");
  }

  /** Add edges to the weighted graph */
  public boolean addEdge(int u, int v, double weight) {
    return addEdge(new WeightedEdge(u, v, weight));
  }

  /** Display edges with weights */
  public void printWeightedEdges() {
    for (int i = 0; i < getSize(); i++) {
      System.out.print(getVertex(i) + " (" + i + "): ");
      for (Edge edge : neighbors.get(i))
        System.out.print("(" + edge.u +
          ", " + edge.v + ", " + ((WeightedEdge)edge).weight + ") ");
      System.out.println();
    }
  }

...
}
```

```
public class TestWeightedGraph {
  public static void main(String[] args) {
    String[] vertices = {"Seattle", "San Francisco", "Los Angeles", "Denver",
        "Kansas City", "Chicago", "Boston", "New York", "Atlanta",
        "Miami", "Dallas", "Houston"};

    int[][] edges = {

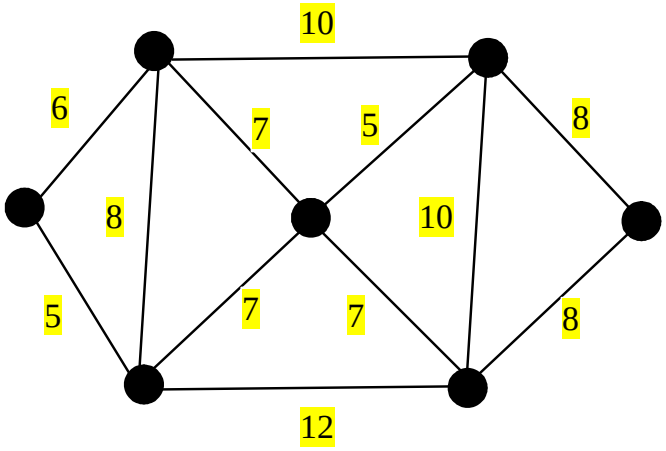
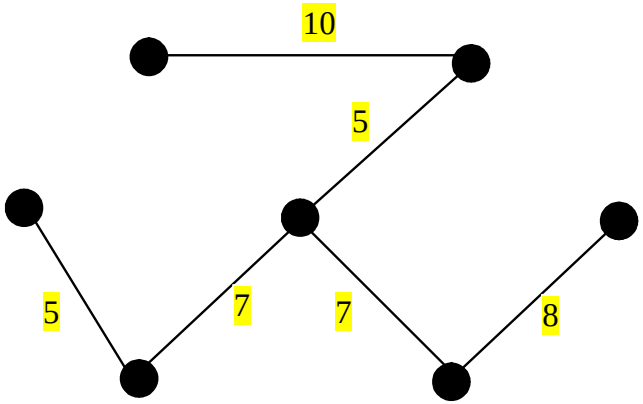
Vertex 4: (4, 2, 5) (4, 3, 6)
```

Minimum Spanning Trees

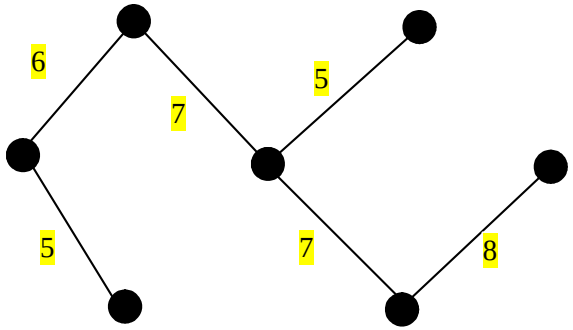
- A graph may have many spanning trees
  - A ***minimum spanning tree*** is a spanning tree with the minimum total weights
  - Application: a company wants to lease telephone lines to connect all the customers together
    - There are many ways to connect all branches together
    - Different lines cost different rates
    - The cheapest way is to find a spanning tree with the minimum total rates

Minimum Spanning Trees

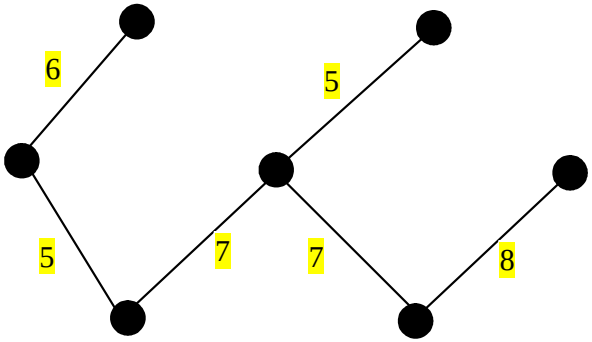




Total w: 42
Not a minimum spanning tree



Total w: 38



Total w: 38

Minimum Spanning Trees

- An algorithm was developed in 1930 by Czech mathematician Vojtěch Jarník and later rediscovered and republished by computer scientists Robert C. Prim in 1957 and Edsger W. Dijkstra in 1959

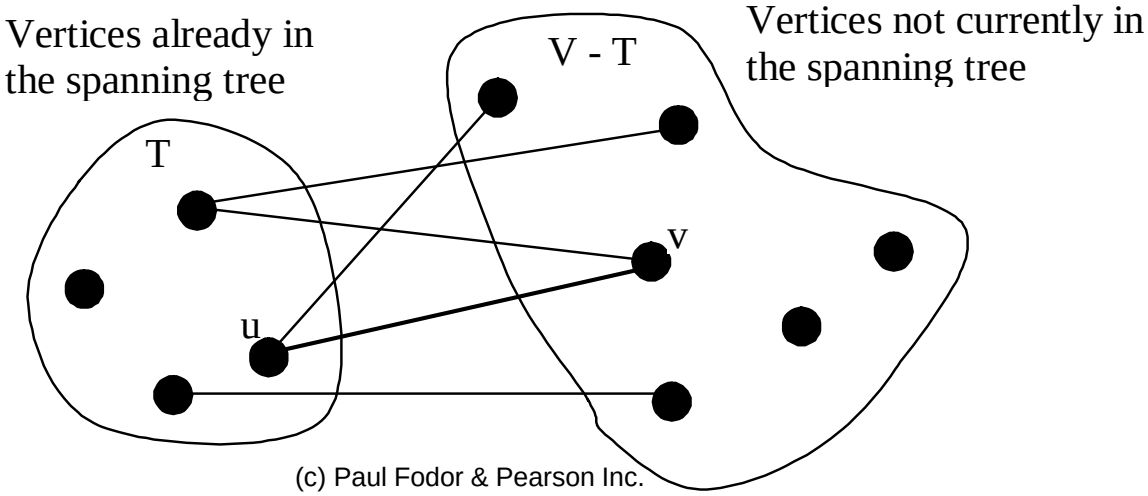
Vojtěch Jarník
1897–1970

Robert C. Prim
1921

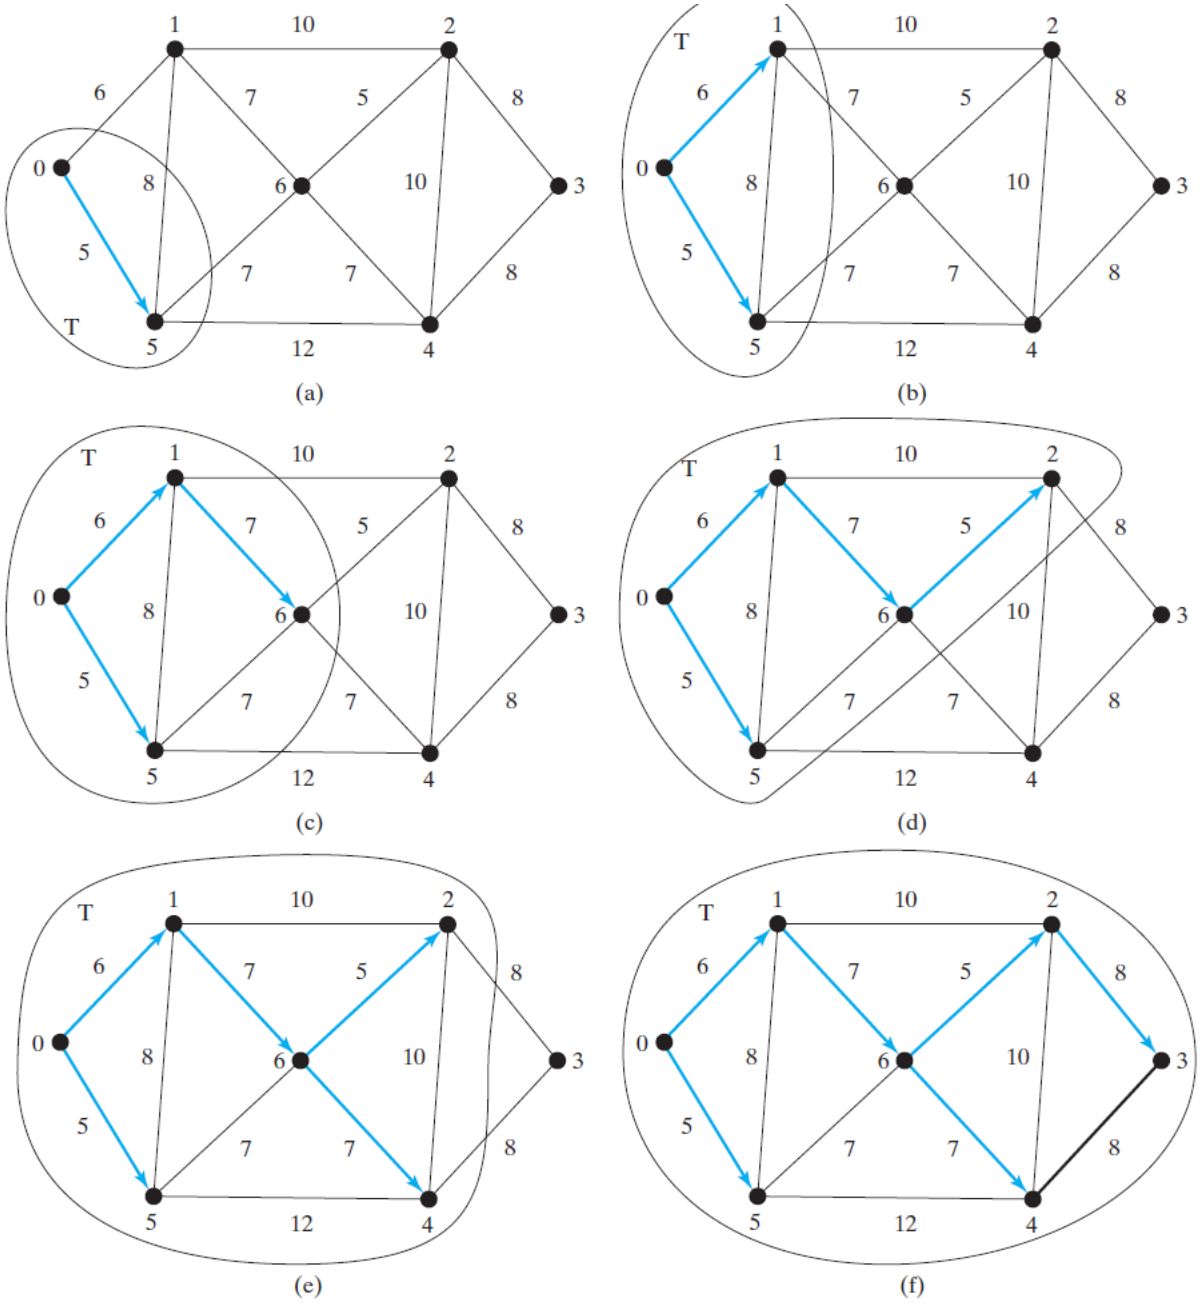
Edsger W. Dijkstra
1930 – 2002

Prim's Minimum Spanning Tree Algorithm

```
Input: G = (V, E, W).
Output: a MST
Tree minimumSpanningTree() {
  Let V denote the set of vertices in the graph;
  Let T be a set for the vertices in the spanning tree;
  Initially, add the starting vertex to T;
  while (size of T < n) {
    find u in T and v in V – T with the smallest weight
      on the edge (u, v), as shown in the figure;
    add v to T;
  }
}
```



Minimum Spanning Tree Algorithm Example



Refined Version of Prim's Minimum Spanning Tree Algorithm

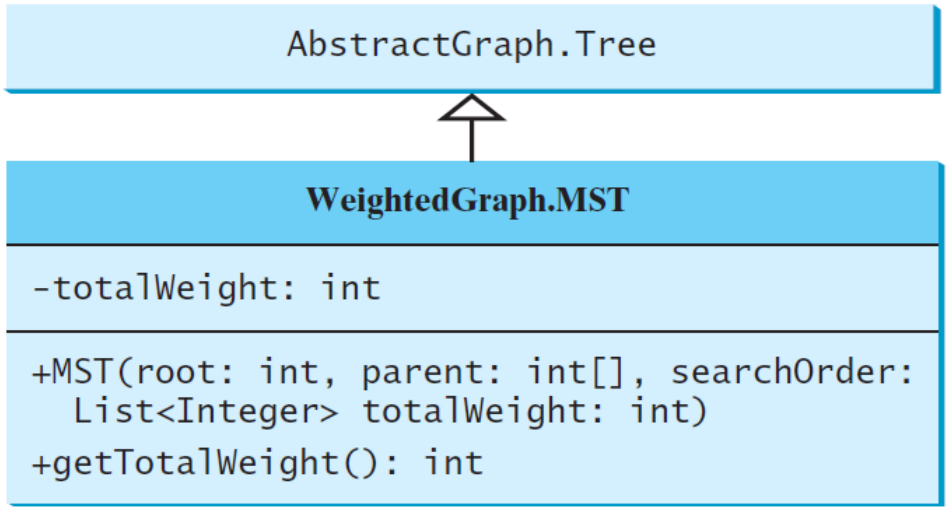
- To make it easy to identify the next vertex to add into the tree, we use **`cost[v]`** to store the cost of adding a vertex **`v`** to the spanning tree **`T`**
- Initially **`cost[s]`** is **`0`** for a starting vertex and assign infinity to **`cost[v]`** for all other vertices
- The algorithm repeatedly finds a vertex **`u`** in **`V - T`** with the smallest **`cost[u]`** and moves **`u`** to **`T`**
  - For all edges **`(u,v)`** where **`v`** in **`V - T`** update the **`cost[v]`** with min between the old cost and the weight of **`(u,v)`**
- Testing whether a vertex **`v`** is in **`T`** by invoking **`T.contains(v)`** takes **`O(n)`** time since **`T`** is a list
  - Therefore, the overall time complexity for this implementation is $O(n^3)$, but it can be reduced to $O(n^2)$ with heaps and hashing.

Refined Version of Prim's Minimum Spanning Tree Algorithm

```
Input: a graph G = (V, E) with non-negative weights
Output: a minimum spanning tree with the starting vertex s as the root
  MST getMinimumSpanngingTree(s) {
   Let T be a set that contains the vertices in the spanning tree;
   Initially T is empty;
   Set cost[s] = 0; and
       cost[v] = infinity for all other vertices in V;

   while (size of T < n) {
     Find u not in T with the smallest cost[u];
     Add u to T;
     for (each v not in T and (u, v) in E)
       if (cost[v] > w(u, v)) {
         cost[v] = w(u, v);
         parent[v] = u;
       }
   }
  }
```

Implementing MST Algorithm



Total weight of the tree.

Constructs an MST with the specified root, parent array, `searchOrder`, and total weight for the tree.

Returns the `totalWeight` of the tree.

```
/** MST is an inner class in WeightedGraph */
public class MST extends Tree {
  private double totalWeight; // Total weight of all edges in the tree
  public MST(int root, int[] parent, List<Integer> searchOrder,
      double totalWeight) {
    super(root, parent, searchOrder);
    this.totalWeight = totalWeight;
  }
  public double getTotalWeight() {
    return totalWeight;
  }
}

/** Get a minimum spanning tree rooted at vertex 0 */
public MST getMinimumSpanningTree() {
  return getMinimumSpanningTree(0);
}

/** Get a minimum spanning tree rooted at a specified vertex */
public MST getMinimumSpanningTree(int startingVertex) {
  // cost[v] stores the cost by adding v to the tree
  double[] cost = new double[getSize()];
  for (int i = 0; i < cost.length; i++)
    cost[i] = Double.POSITIVE_INFINITY; // Initial cost
  cost[startingVertex] = 0; // Cost of source is 0
  int[] parent = new int[getSize()]; // Parent of a vertex
  parent[startingVertex] = -1; // startingVertex is the root
  double totalWeight = 0; // Total weight of the tree thus far
  List<Integer> T = new ArrayList<>();
```

```
  // Expand T
  while (T.size() < getSize()) {
    // Find smallest cost v in V - T
    int u = -1; // Vertex to be determined
    double currentMinCost = Double.POSITIVE_INFINITY;

    for (int i = 0; i < getSize(); i++)
      if (!T.contains(i) && cost[i] < currentMinCost) {
        currentMinCost = cost[i];
        u = i;
      }
    T.add(u); // Add a new vertex to T
    totalWeight += cost[u]; // Add cost[u] to the tree

    // Adjust cost[v] for v that is adjacent to u and v in V - T
    for (Edge e : neighbors.get(u))
      if (!T.contains(e.v) && cost[e.v] > ((WeightedEdge)e).weight) {
        cost[e.v] = ((WeightedEdge)e).weight;
        parent[e.v] = u;
      }
  } // End of while

  return new MST(startingVertex, parent, T, totalWeight);
}
```

```
public class TestMinimumSpanningTree {
  public static void main(String[] args) {
    String[] vertices = {"Seattle", "San Francisco", "Los Angeles",
      "Denver", "Kansas City", "Chicago", "Boston", "New York",
      "Atlanta", "Miami", "Dallas", "Houston"};

    int[][] edges = {
      {0, 1, 807}, {0, 3, 1331}, {0, 5, 2097},
      {1, 0, 807}, {1, 2, 381}, {1, 3, 1267},
      {2, 1, 381}, {2, 3, 1015}, {2, 4, 1663}, {2, 10, 1435},
      {3, 0, 1331}, {3, 1, 1267}, {3, 2, 1015}, {3, 4, 599}, {3, 5, 1003},
      {4, 2, 1663}, {4, 3, 599},{4, 5, 533},{4, 7, 1260},{4, 8, 864}, {4, 10, 496},
      {5, 0, 2097}, {5, 3, 1003}, {5, 4, 533}, {5, 6, 983}, {5, 7, 787},
      {6, 5, 983}, {6, 7, 214},
      {7, 4, 1260}, {7, 5, 787}, {7, 6, 214}, {7, 8, 888},
      {8, 4, 864}, {8, 7, 888}, {8, 9, 661}, {8, 10, 781}, {8, 11, 810},
      {9, 8, 661}, {9, 11, 1187},
      {10, 2, 1435}, {10, 4, 496}, {10, 8, 781}, {10, 11, 239},
      {11, 8, 810}, {11, 9, 1187}, {11, 10, 239}
    };

    WeightedGraph<String> graph1 = new WeightedGraph<>(vertices, edges);

    WeightedGraph<String>.MST tree1 = graph1.getMinimumSpanningTree();

    System.out.println("Total weight is " + tree1.getTotalWeight());
    tree1.printTree();
```

```
    edges = new int[][]{
      {0, 1, 2}, {0, 3, 8},
      {1, 0, 2}, {1, 2, 7}, {1, 3, 3},
      {2, 1, 7}, {2, 3, 4}, {2, 4, 5},
      {3, 0, 8}, {3, 1, 3}, {3, 2, 4}, {3, 4, 6},
      {4, 2, 5}, {4, 3, 6}
    };

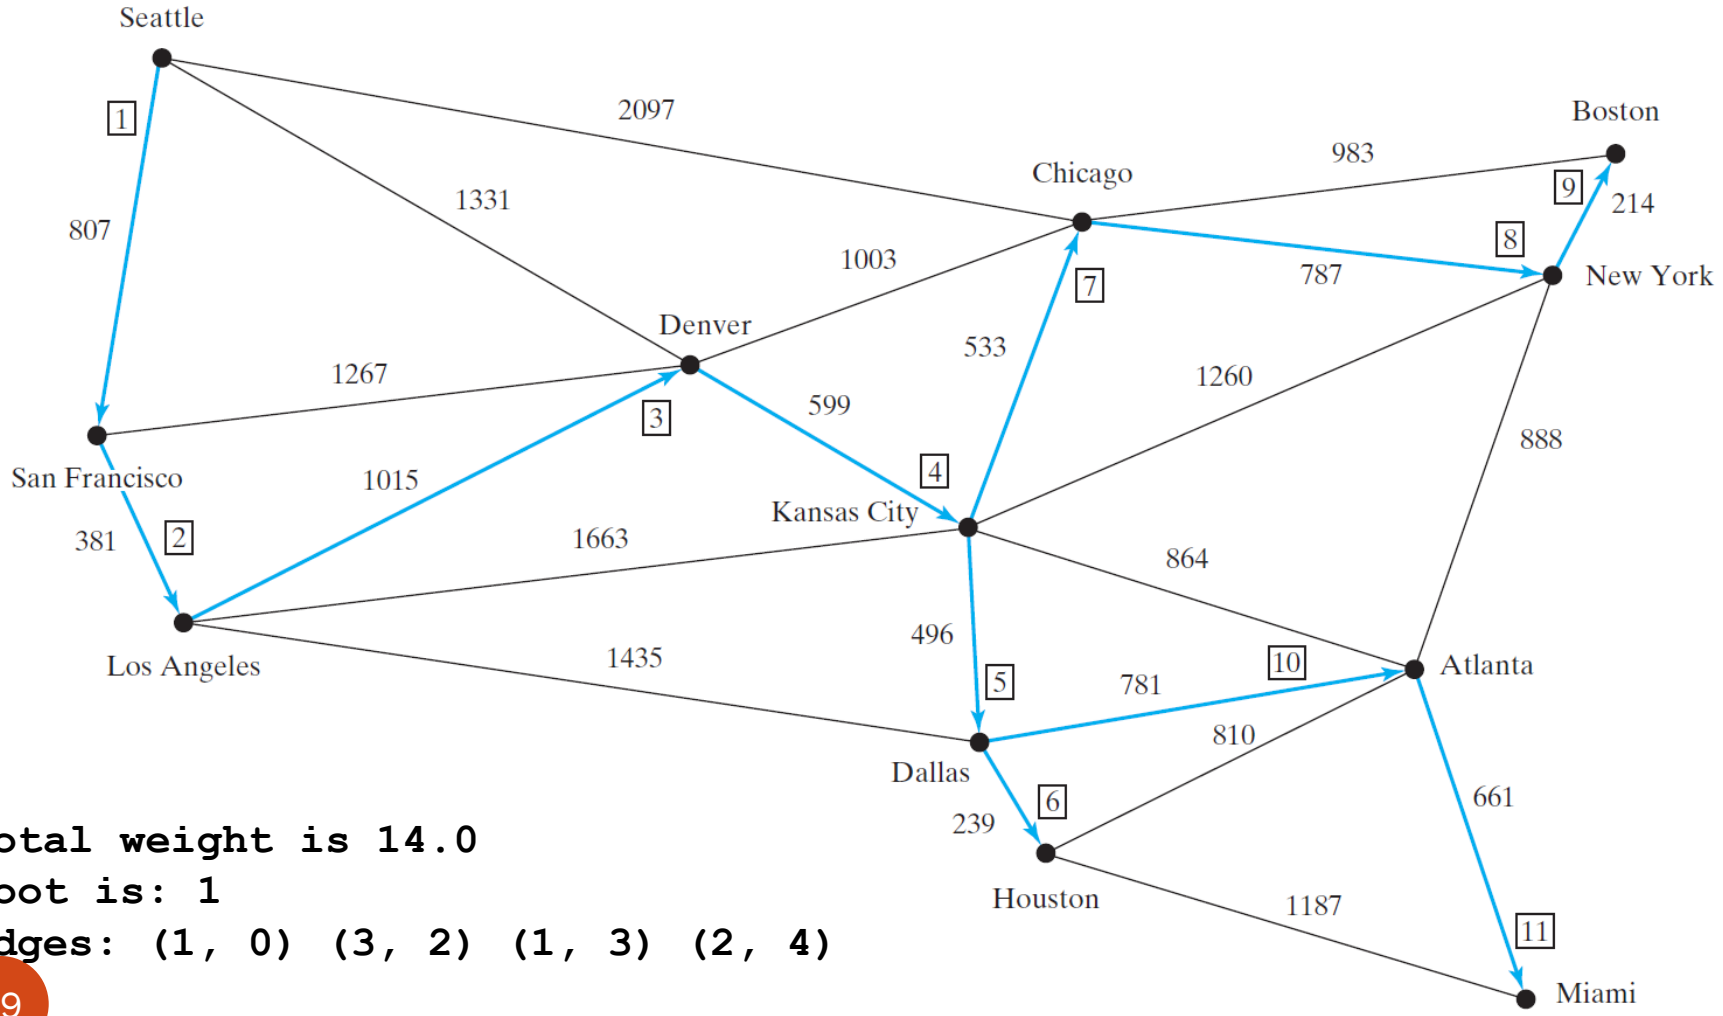
    WeightedGraph<Integer> graph2 = new WeightedGraph<>(edges, 5);

    WeightedGraph<Integer>.MST tree2 = graph2.getMinimumSpanningTree(1);

    System.out.println("\nTotal weight is " + tree2.getTotalWeight());
    tree2.printTree();

  }
}
```

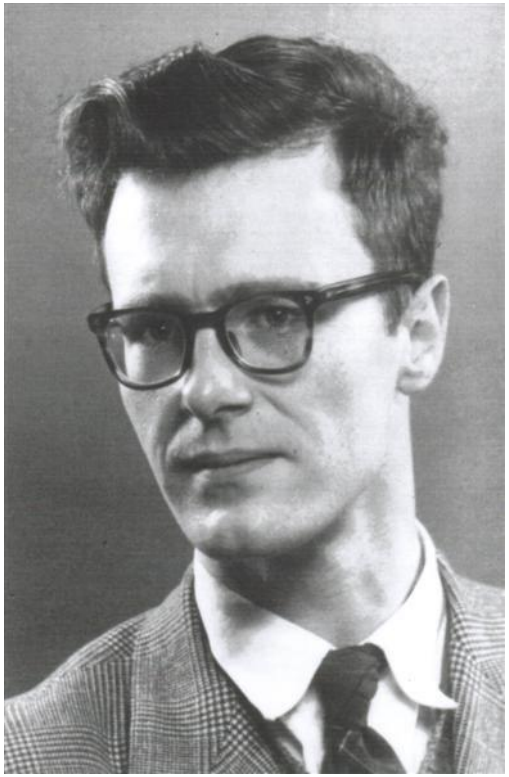
```
Total weight is 6513.0
Root is: Seattle
Edges: (Seattle, San Francisco) (San Francisco, Los Angeles)
 (Los Angeles, Denver) (Denver, Kansas City) (Kansas City, Chicago)
 (New York, Boston) (Chicago, New York) (Dallas, Atlanta)
 (Atlanta, Miami) (Kansas City, Dallas) (Dallas, Houston)
```



```
Total weight is 14.0
Root is: 1
Edges: (1, 0) (3, 2) (1, 3) (2, 4)
```

Shortest Path

- Find a shortest path between two vertices in the graph
  - The shortest path between two vertices is a path with the minimum total weight
- A well-known algorithm for finding a shortest path between two vertices was discovered by Edsger Dijkstra, a Dutch computer scientist
  - In order to find a shortest path from vertex **s** to vertex **v**, Dijkstra's algorithm finds the shortest path from **s** to all vertices
  - Time complexity is $O(n^3)$
    - Can be reduced to $O(n^2)$



Edsger W. Dijkstra
1930 – 2002

Single Source Shortest Path Algorithm

```
Input: a graph G = (V, E) with non-negative weights
Output: a shortest path tree with the source vertex s as the root
   ShortestPathTree getShortestPath(s) {
    Let T be a set that contains the vertices whose
       paths to s are known; Initially T is empty;
    Set cost[s] = 0; and cost[v] = infinity for all other vertices in V;

    while (size of T < n) {
       Find u not in T with the smallest cost[u];
       Add u to T;
       for (each v not in T and (u, v) in E)
         if (cost[v] > cost[u] + w(u, v)) {
           cost[v] = cost[u] + w(u, v); parent[v] = u;
         }
    }
   } // This algorithm is very similar to Prim's for finding a minimum spanning tree
```

Both algorithms divide the vertices into two sets: T and V – T

In the case of Prim's algorithm, set T contains the vertices that are already added to the tree

In the case of Dijkstra's, set T contains the vertices whose shortest paths to the source have been found

Both algorithms repeatedly find a vertex from V – T and add it to T

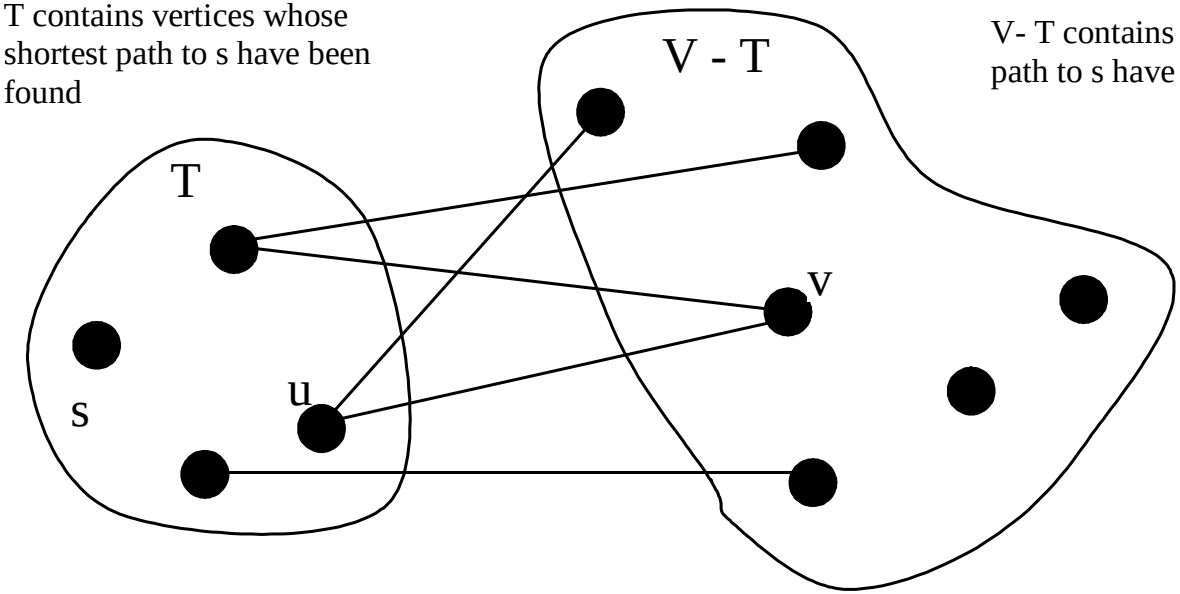
In the case of Prim's algorithm, the vertex is adjacent to some vertex in the set with the minimum weight on the edge

In Dijkstra's algorithm, the vertex is adjacent to some vertex in the set with the minimum total cost to the source

Single Source Shortest Path Algorithm

T contains vertices whose shortest path to s have been found

V- T contains vertices whose shortest path to s have not been found



Single Source Shortest Path Algorithm

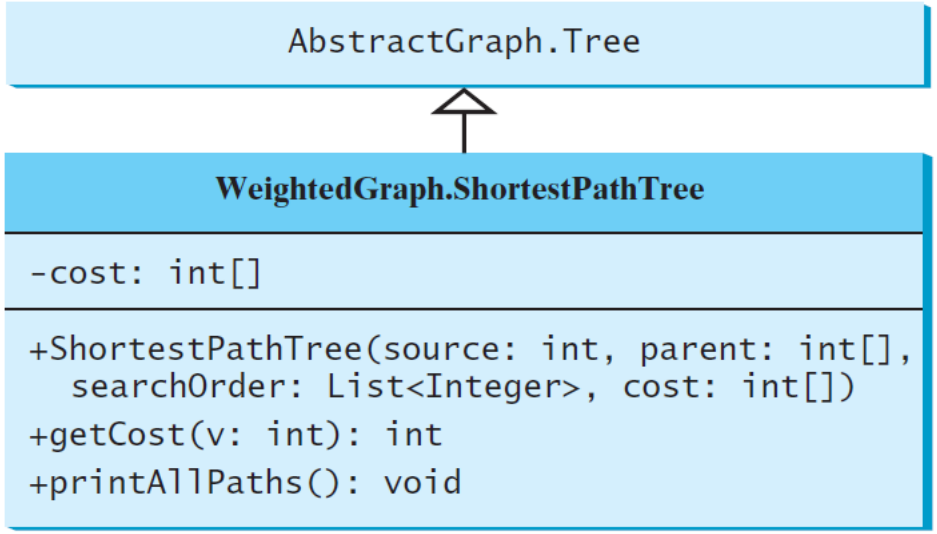
SP Algorithm Implementation



`cost[v]` stores the cost for the path from the source to `v`.

Constructs a shortest path tree with the specified `source`, `parent` array, `searchOrder`, and `cost` array.

Returns the cost for the path from the source to vertex `v`.

Displays all paths from the source.

```
/** Find single source shortest paths */
public ShortestPathTree getShortestPath(int sourceVertex) {
  // cost[v] stores the cost of the path from v to the source
  double[] cost = new double[getSize()];
  for (int i = 0; i < cost.length; i++)
    cost[i] = Double.POSITIVE_INFINITY; // Initial cost set to infinity
  cost[sourceVertex] = 0; // Cost of source is 0
  // parent[v] stores the previous vertex of v in the path
  int[] parent = new int[getSize()];
  parent[sourceVertex] = -1; // The parent of source is set to -1
  // T stores the vertices whose path found so far
  List<Integer> T = new ArrayList<>();
  // Expand T
  while (T.size() < getSize()) {
    // Find smallest cost v in V - T
    int u = -1; // Vertex to be determined
    double currentMinCost = Double.POSITIVE_INFINITY;
    for (int i = 0; i < getSize(); i++)
      if (!T.contains(i) && cost[i] < currentMinCost) {
        currentMinCost = cost[i];
        u = i;
      }
    T.add(u); // Add a new vertex to T
    // Adjust cost[v] for v that is adjacent to u and v in V - T
    for (Edge e : neighbors.get(u)) {
      if (!T.contains(e.v)
          && cost[e.v] > cost[u] + ((WeightedEdge)e).weight) {
        cost[e.v] = cost[u] + ((WeightedEdge)e).weight;
        parent[e.v] = u;
      }
    }
  } // End of while
  // Create a ShortestPathTree
  return new ShortestPathTree(sourceVertex, parent, T, cost);
}
```

```
  /** ShortestPathTree is an inner class in WeightedGraph */
  public class ShortestPathTree extends Tree {
    private double[] cost; // cost[v] is the cost from v to source

    /** Construct a path */

  }

}
```

```
All shortest paths from Chicago are:
A path from Chicago to Seattle: Chicago Seattle (cost: 2097.0)
A path from Chicago to San Francisco:
 Chicago Denver San Francisco (cost: 2270.0)
A path from Chicago to Los Angeles:
 Chicago Denver Los Angeles (cost: 2018.0)
A path from Chicago to Denver: Chicago Denver (cost: 1003.0)
A path from Chicago to Kansas City: Chicago Kansas City (cost: 533.0)
A path from Chicago to Chicago: Chicago (cost: 0.0)
A path from Chicago to Boston: Chicago Boston (cost: 983.0)
A path from Chicago to New York: Chicago New York (cost: 787.0)
A path from Chicago to Atlanta:
 Chicago Kansas City Atlanta (cost: 1397.0)
A path from Chicago to Miami:
 Chicago Kansas City Atlanta Miami (cost: 2058.0)
A path from Chicago to Dallas: Chicago Kansas City Dallas (cost: 1029.0)
A path from Chicago to Houston:
 Chicago Kansas City Dallas Houston (cost: 1268.0)
Shortest path from Houston to Chicago:
 Houston Dallas Kansas City Chicago

All shortest paths from 3 are:
A path from 3 to 0: 3 1 0 (cost: 5.0)
A path from 3 to 1: 3 1 (cost: 3.0)
A path from 3 to 2: 3 2 (cost: 4.0)
A path from 3 to 3: 3 (cost: 0.0)
A path from 3 to 4: 3 4 (cost: 6.0)
```

The Weighted Nine Tail Problem

- The nine tail problem is to find the minimum number of the moves that lead to all coins face down
  - Each move flips a head coin and its neighbors
  - The weighted nine tail problem assigns the number of the flips as a weight on each move
    - For example, you can move from the coins in (a) to (b) by flipping the three coins. So the weight for this move is 3.

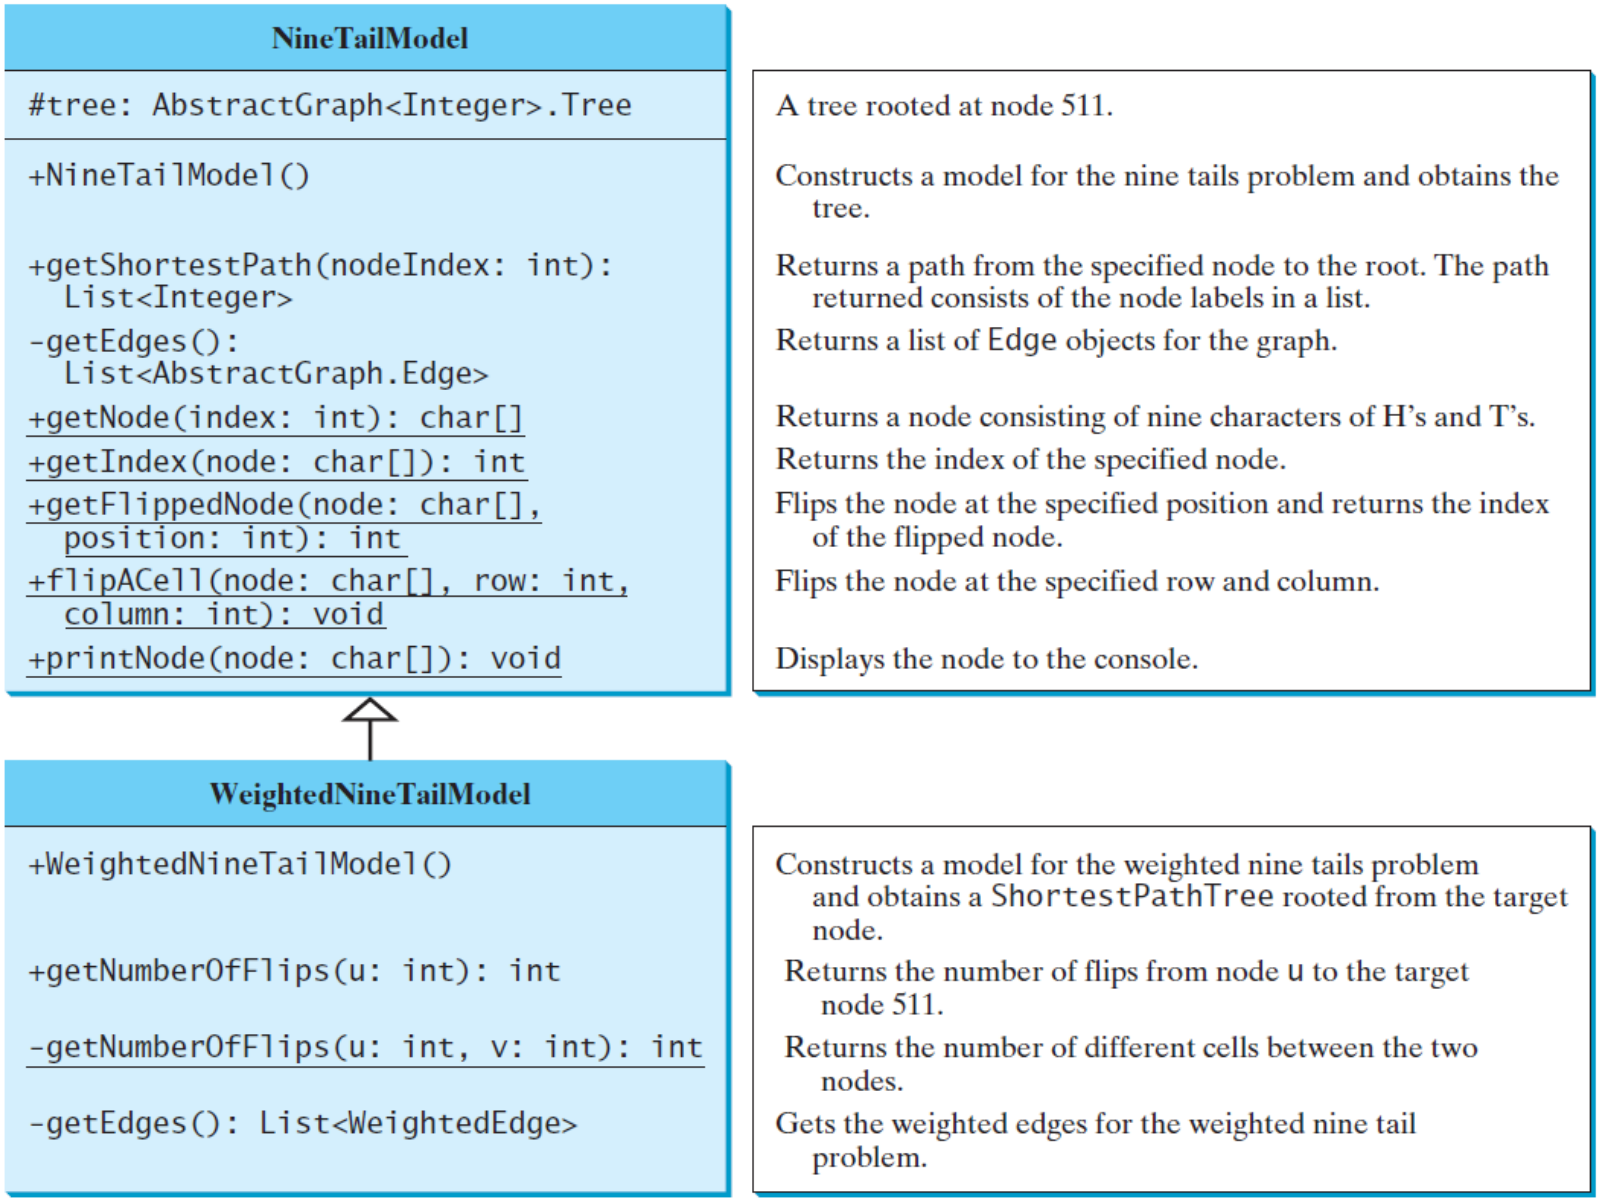
H	H	H
T	T	T
H	H	H

(a)

T	T	H
H	T	T
H	H	H

(b)

WeightedNineTailModel



```
